

## California Mental Health Prevalence Estimates

### Task Team: HSRI, TAC and Expert Consultation From Charles Holzer<sup>1</sup>

In this report, we make use of demographic data from the U.S. Census and the California Department of Finance to describe the target populations for both the Mental Health & Substance Use estimates.

The base description for each area came from the 2000 public use micro data samples released by the U.S. Census to describe public use micro data areas (PUMA). PUMA's have approximately 100,000 people as a minimum, but permit complete cross tabulation of the demographic variables used in the modeling and estimation. The PUMA Data were adjusted to the counties through use of the SF3 (socioeconomic) marginals for the counties and further adjusted by the SF1 marginals, which are primarily Age/Sex/Race. This provided cross-tabulations for Age by Sex by Race by Ethnicity by Martial Status by Education by Poverty by Residential Status. The specific levels are described below.

The basic demographic tables were first created for the year 2000, using the decennial census. Because the main census is completed once a decade there is need for updates to account for population changes between decades. Two different series of updates are available. One series created by the U.S. Census Bureau is called estimates, which provides updates for age categories, sex, and race/ethnicity is based on information like Births, Deaths, Building Permits, & School Enrollment during the following year. An alternative series of updates, provided by the California Department of Finance is based on projections from earlier years to future years based on expected growth. It provides age by sex by race/ethnicity for future years through growth models. These are used in the present series of estimates. It must be noted that neither the estimates nor projections series provide new data on the other variables of interest such as marital status, education, poverty, or residential status. Therefore those components of the full table are carried forward within the age by sex by race/ethnicity groups within the present report.

In 2010, a new decennial census was completed by the U.S. Census Bureau. The results of that census were not yet available in a form we could use to update the present denominator tables, even for the variable in that census. But it must be noted that the 2010 decennial census is essentially limited to basic demographics and no longer collects the socioeconomic information such as education, income, and poverty. The socioeconomic data are not in the constitutional mandate for the census, which is to allocate the distribution of congressional districts by population. Instead, the socioeconomic information is now collected primarily in the annual American Community Survey (ACS) and reported by PUMAs rather than counties. We are in the process of incorporating the ACS into our estimates but have not accomplished that yet. Therefore, the demographic model used to create denominators for both mental health and substance use or abuse is as follows.

---

<sup>1</sup> The methodology used here has been used for California in previous years for mental health and documented at [www.charles.holzer.com](http://www.charles.holzer.com)

## *Details for Demographic Cells*

The following demographic variables will be used in the prevalence tables:

### Age

Age is available in the census and the survey, and has been shown to be strongly related to the prevalence of mental disorders. We have divided age into ten categories. These categories are: 0-5,6-11,12-17,18-20,21-24,25-34,35-44,45-54,55-64,65+.

### Sex

Sex is an important risk factor for psychiatric disorder and is available from the Census.

### Race and ethnicity

For the current estimates we have implemented an expanded definition for Race/Ethnicity, which is based on the 2000 Census. This census iteration permits respondents to identify multiple race or ethnicity categories. This revised categorization includes 1) White, 2) African American, 3) Asian, 4) Pacific Islander, 5) Native American or Alaskan Native, 6) Other races, 7) Multiple races specified, 8) Hispanic. Although reported by the Census, we do not have sufficient mental health data corresponding to each of these categories and have used the closest group available. For example, the rates for Asians are still used for Pacific Islanders, although the numbers in that category can now be identified.

### Marital Status

Marital status is defined in the Census for persons age 15 or older. It differentiates married, separated, widowed, divorced, and never married. To reduce the numbers of cells we have combined separated, widowed, and divorced. This appears to work because the groups are largely differentiated by age. This variable is used in the adult tables only.

### Education

For the present analyses we have trichotomized education into less than high school graduation, high school graduate through some college, and college graduate. These data are available for age 18 years or older.

### Poverty

Poverty status is divided into five categories: Below 100% of the federal poverty level, 100%-199%, 200%-299%, 300% +, and undefined. The undefined category includes mostly unrelated children (e.g. children in foster homes), institutions and most group quarters.

## Residential setting

The mental health and substance use surveys included only persons in residential households. We have maintained household residences, institutions, and group quarters as separate strata in the demographic matrix. Estimates for institutional and group quarters were based on the corresponding residential rates with adjustments for the proportions of that county falling into the various residential categories provided by the census. For example the 2000 census reported total numbers within a county in hospitals, mental hospitals, prisons, juvenile justice, nursing homes, college dorms, military housing and homeless shelters, but did not differentiate them by demographic variables other than age and sex. Adjustment rates for these categories were merged into weighted averages for institutional and for other group quarters within age and sex and were applied relative to the corresponding residential rate.

### *Estimation of Need for Services*

The estimation of need for mental health and substance abuse services requires a definition of need, a source of data about that need, and a statistical method to complete the estimates. Historically, need was a projection based on utilization of services, but that approach is somewhat circular in that it does not allow for unmet need without assuming parity among groups. In a monograph edited by Goldsmith and colleagues (1988), entitled *Needs Assessment: Its Future*<sup>2</sup>, the distinction is made between Direct and Indirect Needs Assessment. Direct assessment presumes that data about need are collected in the place for which estimates are required. Ideally, this would be a survey with appropriate assessments. Unfortunately there are few prevalence surveys of states and counties and even fewer with adequate diagnostic instruments. Thus, we cannot provide direct estimates of need. Therefore we consider a different estimation approach in which the Goldsmith monograph would be called "Indirect Estimation". The task for indirect estimation is to make use of the information known about need from one source, such as the National Comorbidity Study (NCS) sample, and to project it on to other populations, such as a state, county or city. Such estimates can also be made for smaller geographic areas. Our methods for making those projections are presented below.

### *Indirect Estimation*

An estimation method is considered indirect if it estimates need without making an adequate number of direct assessments, i.e. interviews, in the target population. Two situations arise. In the first, estimates of need are made when there are no direct assessments from which to work, so variables such as risk factors, socioeconomic status, and related social problems are used to make an estimate. For example, one might project that mental health services are needed in areas with high crime, poverty, divorce, teenage pregnancy, and child abuse. That approach is called the social indicators approach, and is not the method being used here. The second indirect estimation method is one in which a direct estimate is available for one population but must be applied to another. That approach is our present focus. A more complete description of this approach is included in the section below.

---

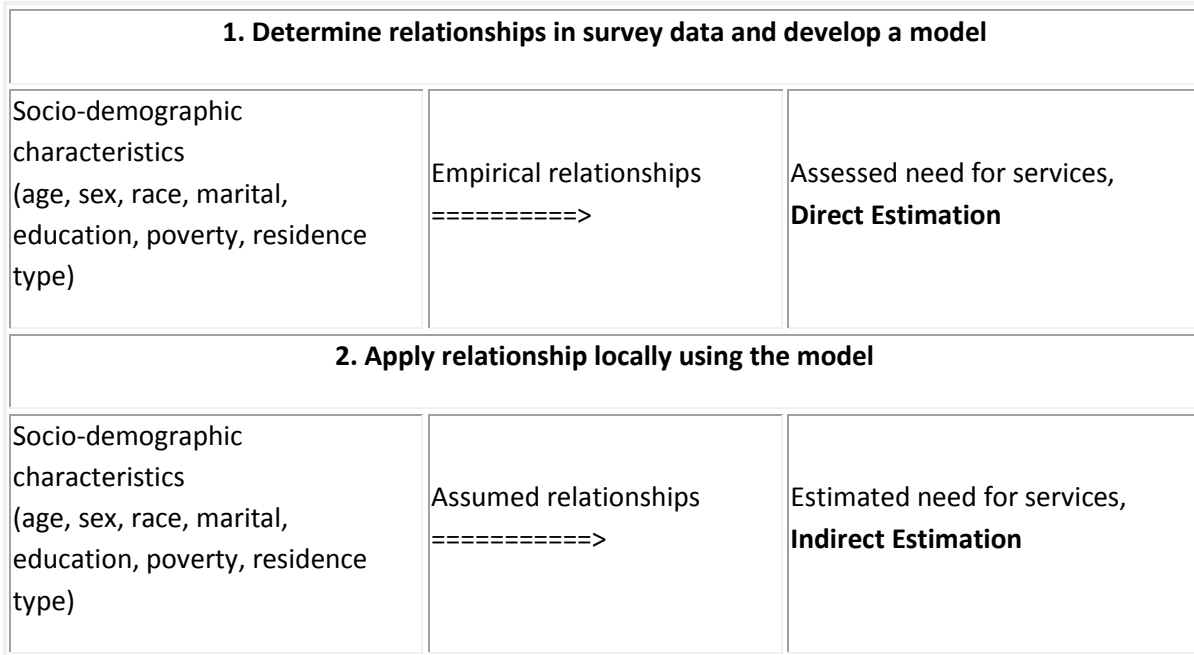

<sup>2</sup> Rockville, Md. : U.S. Dept. of Health and Human Services, Public Health Service, Alcohol, Drug Abuse, and Mental Health Administration, Nation Institute of Mental Health, Division of Biometry and Applied Sciences, 1988

**Overview of the Indirect Estimation Approach**

The basic assumption underlying indirect needs assessment is that demographic characteristics have a consistent general relationship to mental health or substance use disorders throughout the U.S. That is to say, persons with particular demographic characteristics are more likely than others to need mental health or substance abuse services, regardless of where they live. Thus, through use of indirect standardization one should be able to apply average estimates of need for persons of a particular type to other people of that type. This approach assumes that demographic variation is more important than geographic variation. By making estimates for specific demographic subgroups and then summing the estimates across all demographic subgroups, an overall estimate of the number of people in need of mental health services can be calculated.

Figure 1 illustrates the concept of indirect estimation in general.

**Figure 1: Illustration of Extrapolation Paradigm**

While the basic idea is a simple one, the actual procedures for indirect estimation are somewhat complex. The remainder of this section provides an outline and some details for the various steps in this technique. Note that the procedures for estimates deal with the populations covered by the specific survey, but also must have methods for generating estimates for populations not covered in the original prevalence survey being used. These include procedures for children (e.g. below age 18), elderly, in the case of NCS, persons age 55 and older, and institutional populations such as prisons, hospitals, college dorms, and even military housing.

## Mental Health Prevalence Rates

### *Mental Health Prevalence Rate Methodology*

We have produced mental health need (SED) estimates for children below 18 years of age primarily based on poverty levels. This is because there are no national surveys comparable to those used for the adult estimates that cover the full age range necessary for our purposes. The estimation strategy relates to the state level methodology reported in the Federal Register, but is modified based on the poverty level of children within county or state<sup>3</sup>.

The estimates for adults are synthetic estimates from the Collaborative Psychiatric Epidemiology Surveys (CPES). The CPES combines data from three national surveys: The National Comorbidity Survey Replication (NCS-R), the National Survey of American Life (NSAL) and the National Latino and Asian American Study (NLAAS). These surveys were designed to use a common core psychiatric diagnostic instrument, the Composite International Diagnostic Instrument (CIDI) sponsored and published by the World Health Organization. The data from the three surveys are weighted to provide appropriate representation for the U.S. The diagnoses and related impairment data are combined to create summary levels of need for mental health services – the MHN definitions. The definition for the mental health needs (MHN) categories consists of groupings of DSM-IV diagnoses and the level of impairment or disability. Impairment is measured by the Sheehan Disability Scale<sup>4</sup>. The Sheehan Disability Scale measures the extent a mental disorder interferes with home management (like cleaning, shopping and taking care of the house), a person's ability to work, a person's ability to form or maintain close relationships with other people, and with a person's social life. This self-rating scale ranges from zero to ten with 7 corresponding to severe impairment. We scored it by taking the average of the four areas assessed. In a second measure of disability, respondents were asked to report the number of days in the last year that activities are limited due to the disorder. Either the Sheehan or the disability days could satisfy the impairment for the MHN definition.

The model provides prevalence estimates by age, sex, race, marital status, education, poverty and residential setting. The logistic regression models used for the present estimates were created using SAS Procedure Catmod. Each dependent variable was inverted to estimate need. Independent variables were modified to have adequate numbers in the anchor category for each variable. The age group index was used as a direct effect and a centered then squared version of the age was entered to account for higher rates in the middle age categories and lower rates for younger and older respondents. The model-based risk models were applied to each of the cells in the full demographic matrix, except for children under 18 and for non-residential status as noted above.

The tables presented in this report use two definitions of mental illness for adults. The first is a relatively narrow definition of severity that is similar to commonly used definitions of severe mental illness for adults. The numbers are calculated using the criteria listed under the column labeled MHN2 on Table 1. The second set of estimates (MHN4) uses expanded inclusion criteria and produces estimates that include

<sup>3</sup> Federal Register: October 6, 1997 Volume 62, Number 193 (fr06oc97-78)

<sup>4</sup> [http://www.cqaimh.org/pdf/tool\\_lof\\_sds.pdf](http://www.cqaimh.org/pdf/tool_lof_sds.pdf)

individuals from the first level as well as those with less severe conditions in terms of disability level and disability days.

### *Details for Table Columns*

The following population columns will be used in the prevalence tables:

#### Total Population

Total population includes individuals living in households, institutions, and other group quarters.

#### Household Population

Household population is comprised of individuals living in households only.

#### Households below 200% poverty

Households in this column are comprised of Individuals living in households at or below 200% of the federal poverty level.

#### Cases

The number of cases is equivalent to the number of people who meet the demographic and mental health diagnosis criteria.

#### Population

The population column represents the number of individuals living in the area who meet the demographic criteria.

#### Percent

Percent represents the percentage of individuals within the area who meet the demographic and mental health diagnosis criteria.

### *Limitations*

For the adult estimates, the CPES did not assess schizophrenia or other psychotic disorders, and thus limits the prevalence estimates to the disorders shown in Appendix A, Table 1. The NLAAS, which focuses on Hispanics and Asian Americans, did not inquire about mania or specific phobia. We have used statistical models to adjust for these omissions.

Due to the fact that the rates presented here are based on census data that only use particular categories, important demographical groups such as same sex partnerships, certain race/ethnicity categories, etc., may not be adequately represented.

## ***California Mental Health Prevalence Estimates: State and County Levels***

### **Statewide Estimates**

Tables 2 through 6, located in Appendix A, Section I, present statewide estimates for the prevalence of mental illness within California. Table 2 displays prevalence rates for children ages 0-17 with serious emotional disturbances. For youth, the prevalence rate is 7.56% (n=714,431). Prevalence is split fairly evenly across age and gender categories. Hispanic youth have a slightly higher estimated prevalence rate of 8.03% as compared with 6.85% for white youth (non-Hispanic). African American and Native American youth also have a slightly higher prevalence rate of 7.99% and 7.91% respectively. Predictably, prevalence varies with income level with higher levels among youth from the lower income categories.

Table 3 displays prevalence figures for adults with the more narrow definition of severe mental illness. The narrow definition of severe mental illness for adults yields a total of 1,178,513 individuals statewide, 4.28% of the adult population. Prevalence among adults increases with age between the ages of 18-20 and 35-44, ranging from 1.98% of the population for individuals ages 18-20 to 6.23% of the population among individuals ages 35-44. Rates are higher among females (4.94% for females vs. 3.62% for males), Native Americans (7.02%), and individuals who are separated, widowed or divorced (6.93%). Prevalence tends to decrease as education level increases and as income increases.

Table 4 contains an expanded definition of severe mental illness for adults using an extended array of diagnoses and yields a total of 4,361,574 individuals (15.85%). The distribution across demographic categories follows a similar pattern to the one described above.

### **California Statewide Estimates Compared with other States**

Tables 5 and 6, found in Appendix A, Section I, display prevalence estimates across all states and the District of Columbia for youth with severe emotional disturbance and adults with severe mental illness. In these tables, States are ordered from lowest to highest rate.

State prevalence data for youth are displayed in Table 5. Prevalence rates for States range from a low of 6.91% in New Hampshire to a high of 7.93% in Mississippi. California, with a prevalence rate of 7.44 for children ages 0-17, falls approximately in the middle of the distribution with a rank of 28.

Table 6 shows similar data for adults with serious mental illness. State prevalence rates range from a low of 3.26% in Hawaii to a high of 5.79% in Mississippi. Unlike with the children's estimate, California falls close to the lower end of the distribution for adults with SMI with a prevalence rate of 4.28%, giving the state the ninth lowest rate in the country.

### **California County Estimates**

Tables 7 and 8, located in Appendix A, Section I, display prevalence rates for each California County, for both adult severity categories. Table 7, which includes data for the more restricted definition of severe mental illness, displays a range across counties from a low of 3.82% in San Mateo County to a high of 8.69% in Lassen County.

Breakdowns of County level prevalence estimates for both levels of severity, by demographic categories, are contained in Appendix A, Section II.

## Substance Use Prevalence Rates

The overall CPES focused on adults although a supplement looked at adolescents. A much larger survey focusing on substance use and abuse is the National Survey of Drug Use and Health (NSDUH) sponsored annually by the Substance Abuse and Mental Health Services Administration (SAMHSA). To make substance use prevalence estimates for California and counties, we have used the 2009 data from the NSDUH. The overall sample included 55,772 people age 12 and older that were interviewed using computer aided interviews. Most interviews were face-to-face but alternatives were used to maximize response. The details of the methods are provided on the SAMHSA archive at the University of Michigan along with the public use version of the data set. Because of the timeline of this project we have used the public use version of the data, which do not provide local geographic identifiers to the state or county level. Thus the strategy has been to link the demographic characteristics between the NSDUH survey and the demographics for California counties to produce synthetic estimates in a manner parallel to the CPES estimates for adult mental health. We have not made substance use estimates for younger children where prevalence rates are smaller but still of concern.

Because the demographic coding in the NSDUH had some differences from our denominators for California, we used modest adjustments in applying the risk models from NSDUH to the demographic categories. The age categories for NSDUH for ages 35-64 spanned 15 years rather than the ten-year increments. Also poverty had cuts at 100% and 200% but not 300%. We estimated rates for 300% or higher by using the income category of greater than \$75,000. For the dependent variables from the NSDUH, we selected alcohol abuse and dependence, and summarized abuse of cocaine, heroin, sedatives, stimulants, hallucinogen, inhalant, tranquilizers, marijuana, and painkillers. Although we distinguished abuse from dependence, in the summaries, it was possible for a respondent to report abuse of one drug and dependence on another. The abuse and dependence summaries are not mutually exclusive as they would be for a single drug. For the present report we have not included the any use variables, the serious psychological distress or the Kessler K6 indicators.

For each of the dependent drug use summaries we constructed logistic regression models using SAS Proc Catmod. The present models use each demographic in the model as a categorical main effect, with categories reversed to insure a large enough anchor category. The dependent variable coded with no disorder was used as the denominator. The exception to this coding was that age (category) was entered as a direct rather than categorical effect and a centered squared version of age was included to permit higher prevalence in young adults and lower prevalence for older or younger respondents. The models were used to generate risk levels for each of the county demographic cells and summaries of those risks were presented in the summary tables. This is parallel to the methods for the CPES. There is no specific parameter in the models for residential type as institution or group quarters. Adjustment factors were created "from the literature" as adjustments for prisons, nursing homes, military, or college dorms. Those were averaged based on the residential status mix and applied as an average inflator for people in institutional or group quarters in a particular county. The relationship of such inflators for mental health versus substance abuse is subject to review and revision.

The summary tables for NSDUH based estimates parallel those for the mental health CPES tables.
